Abstract- The first problem in our third millennium is energy. For this raison, we try to find a new solution to develop different ways of distribution and energy use. This article presents the design of a sliding mode controller using sliding mode observation technique which aims to simplify the control procedure. For ameliorating the quality of the energy transferred from the power supply to the load, and minimizing the harmful effects of the harmonics generated by nonlinear load. The virtual grid flux vector estimated in the sliding-mode observer yields robustness against the line voltage distortions. We propose a new multi-function converter as an efficient solution to improve the power quality. The good dynamic and static performance under the proposed control strategy is verified by simulation and experiment.

Keywords- Harmonics, Three phase APF, PWM rectifier, DPC, virtual line flux linkage observer, MVBPF, PV, sliding mode(SM), SMO (Sliding Mode Observer).

1. Introduction

Photovoltaic is the most direct way to convert solar radiation into electricity. The generation of electricity is based on the photovoltaic effect, which was first observed by Henri Becquerel [6] in 1839. It is the technological symbol for a future sustainable energy supply system in many countries. A considerable amount of money is invested in research, development and demonstration; several governments set up substantial market introduction programs and industry invests in larger production facilities. This is a remarkable situation since at the same time photovoltaic (PV) electricity is regarded as much too expensive compared to conventional grid electricity.

Sliding mode observation and control schemes for both linear and nonlinear systems have caused considerable interest in recent times. Discontinuous nonlinear control and observation schemes, based on sliding modes, exhibit fundamental robustness and insensitivity its properties of great practical value [1].

For ultime goal of reducing the overcrowding and elevate the performance in treating the energy of power system. This work gives a supplementary function to power converter for making sure it work also an active filter.

2. Custom Power Devices

All custom power devices are capable of providing a number of power quality functions which can be employed selectively or simultaneously.

2.1. Control of PWM Rectifier with Active Filtering Function

Nowadays, harmonic pollution in electrical power systems due to nonlinear loads such as AC-to-DC power converters has become a serious problem.

To eliminate or reduce harmonics in the power systems, a number of methods have been developed and put into practice. Active power filters and PWM rectifiers are two typical examples of these methods. The active power filter
and PWM rectifier have basically the same circuit configuration and can operate based on the same control principle.

**Sliding-mode current observer for virtual grid flux**

The aim of Virtual Flux (VF) approach is to improve the VOC (Voltage Oriented Control) [2]. The Sliding-Mode Direct Power Control technique with the pseudo-sliding mode DC-link voltage controller presented in Fig (1) has been examined in the simulation and experimental research. For the PWM rectifier the inductor voltages $v_L$ and the converter input voltages $v_f$ balance the grid voltages $v_s$ according to the matrix equation

$$v_s = v_L + v_f$$  \hspace{1cm} (1)

The (a-b) components of the converter voltage vector $v_f$ can be estimated out of the dependence involving the DC-link voltage and the PWM pattern:

$$v_f = \frac{2}{3} U_c \left(S_a - \frac{1}{2}(S_b + S_c)\right)$$  \hspace{1cm} (2)

The sliding mode observer uses the system model with the sign feedback function. The continuous time version of the SMO (Sliding Mode Observer) is described by Equation (3).

$$\frac{d}{dt} \begin{bmatrix} i_{fa} \\ i_{fb} \end{bmatrix} = \frac{1}{L_f} \left(\lambda \text{sign} \left[ \begin{bmatrix} i_{fa} - i_{feast} \\ i_{fb} - i_{feast} \end{bmatrix} \right] - R_f \begin{bmatrix} i_{fa} \\ i_{fb} \end{bmatrix} \right)$$  \hspace{1cm} (3)

The estimated values of the grid voltage are obtained from the low-pass filter:

$$\begin{bmatrix} v_{fasteSMO} \\ v_{betaSMO} \end{bmatrix} = \text{LPF} \left(\lambda \text{sign} \left[ \begin{bmatrix} i_{fa} - i_{feast} \\ i_{fb} - i_{feast} \end{bmatrix} \right] \right)$$  \hspace{1cm} (4)

While the ($\alpha$-$\beta$) components of the virtual grid flux are calculated as follows:

$$\varphi_{s\alpha} = \int \text{sign} \left[ \begin{bmatrix} i_{fa} - i_{feast} \\ i_{fb} - i_{feast} \end{bmatrix} \right] dt + \varphi_{s\alpha0}$$  \hspace{1cm} (5)

Where $\lambda$ is the positive constant.

Hence the structure of the virtual grid flux sliding-mode observer presented in Fig 2.

$$\begin{bmatrix} \sigma_{\alpha} \\ \sigma_{\beta} \end{bmatrix} = \begin{bmatrix} i_{fa} - i_{feast} \\ i_{fb} - i_{feast} \end{bmatrix}$$  \hspace{1cm} (6)

The sliding mode will exist only if the following condition

$$\sigma_{\alpha} \sigma_{\beta} < 0$$  \hspace{1cm} (7)

The instantaneous active and reactive powers are estimated in the block (power observer) by measurement of line current and the estimation of the virtual flux components $\varphi_{\alphaest}, \varphi_{\betaest}$ [13].

$$\begin{bmatrix} P_{\alphaest} \\ Q_{\alphaest} \end{bmatrix} = \omega \begin{bmatrix} \varphi_{\alphaest} i_{fa} - \varphi_{\alphaest} i_{fa} \\ \varphi_{\alphaest} i_{fa} - \varphi_{\alphaest} i_{fa} \end{bmatrix}$$  \hspace{1cm} (8)
The command reactive power $q_{\text{ref}}$ and (delivered form the outer sliding mode DC-link voltage controller) active power $P_{\text{ref}}$ values are compared with the estimated $q$ and $p$ values, in reactive and active powers hysteresis controllers, respectively.

If $(q_{\text{ref}} - q > H_q)$, $d_q = 1; \text{ Else }, d_q = 0$;

If $(p_{\text{ref}} - p > H_p)$, $d_p = 1; \text{ Else } d_p = 0$; (7)

$H_p$ and $H_q$ are the hysteresis band. Table I shows the switching table for VF-DPC control.

With: $V_{d}(000), V_{d}(111), V_{d}(100), V_{d}(110), V_{d}(010), V_{d}(011)$ $V_{d}(001), V_{d}(101)$.

$$I = I_{sc} - I_0 \left( e^{(V + IR)/q} - 1 \right) - \frac{V + IR_{sc}}{R_{sh}} \quad (8)$$

With $I$ and $V$ are respectively the PV current and voltage, $I_0$:leakage or reverse saturation current $q$: electron charge, $n$: ideality factor, K is the Boltzman’s constant ($1.38.10^{-23}$ J/K), $R_{sc}$ :series cell resistance , $R_{sh}$:shunt cell resistance.

B. Boost converter

The Boost converter shown in Figure 4, it has step-up conversion ratio. Therefore the output voltage is always higher than the input voltage. The converter will operate throughout the entire line cycle, so the input current does not have distortions and continuous. It has a smooth input current because an inductor is connected in series in with the power source. In addition the switch is source-grounded; therefore it is easy to drive.

With $\alpha$, $\beta$, $\theta_5$, $\theta_7$, $\theta_6$, $\theta_8$, $\theta_9$, $\theta_{10}$, $\theta_{11}$, $\theta_{12}$.

$$I_{sc} = -\frac{V + IR_{sc}}{R_{sh}} \quad (8)$$

A three phase voltage inverter is used to interface the PVG with the grid by converting the dc power generated by the PVG into AC power to be injected to the grid. The
dynamic model of a PWM DC-AC Converter can be
described in the well known (d-q) frame through the Park
transformation as follows [1], see appendix:

\[
\frac{di_{fd}}{dt} = -\frac{R_f}{L_f}i_{fd} + \frac{1}{L_f}v_{fd} - \frac{v_{sd}}{L_f} \\
\frac{di_{fq}}{dt} = -\frac{R_f}{L_f}i_{fq} + \frac{1}{L_f}v_{fq} - \frac{v_{sq}}{L_f} \\
\frac{dU_c}{dt} = \frac{d_d}{C}i_{fd} + \frac{d_q}{C}i_{fq}
\]

(9)

Where

\[d_d, d_q - \text{Axis and } q\text{-axis switching state functions,}
\]

\[\hat{v}_{sd}, \hat{v}_{sq} - d\text{-Axis and } q\text{-axis supply voltages.}
\]

The bi-directional characteristic of the converter is very
important in this proposed photovoltaic system, because it
allows the processing of active and reactive power from the
generator to the load and vice versa, depending on the
application. Thus, with an appropriate control of the power
switches it is possible to control the active and reactive
power flow.

\[\frac{\hat{v}_d}{\hat{v}_q} = \begin{bmatrix} \frac{1}{i_{fd}^2 + i_{fq}^2} \begin{bmatrix} i_{fd} & -i_{fq} \end{bmatrix}^T \end{bmatrix}_{P}^T \begin{bmatrix} i_{fd} & i_{fq} \end{bmatrix}^T \begin{bmatrix} i_{fd} & i_{fq} \end{bmatrix}
\]

(10)

Where \(\hat{v}_d\) and \(\hat{v}_q\) are the estimated main line

\[K_{SMP} = \begin{bmatrix} k_{SMPd} & 0 \\ 0 & k_{SMPq} \end{bmatrix}; K_{SM} = \begin{bmatrix} k_{SMd} & 0 \\ 0 & k_{SMq} \end{bmatrix}
\]

Where \(k_{SMPd}, k_{SMPq}, k_{SMd}\) and \(k_{SMq}\) are positive constants and consequently, their temporal
derivatives are given by:

\[\dot{\hat{S}} = K_{SMP}\dot{E_f} + K_{SM}\dot{E_f}
\]

(14)

The equivalent control can be calculated from the
formula \(\hat{S} = 0\), and the stabilizing control is given to
guarantee the convergence condition (13).

\[\dot{\hat{S}} = K_{SMP}\dot{E_f} + K_{SM}(AI + Bu - G) = 0
\]

(15)

The equivalent control \(u_{eq}\) is deduced by imposing the
sliding regime condition \(\hat{S}\) obtaining:

\[u_{eq} = \begin{bmatrix} u_{eqd} \\ u_{eqq} \end{bmatrix} = (K_{SMP}B)^{-1}\left[ K_{SM}E_f - K_{SMP}(AI + Bu - G + \dot{I}^*) \right]
\]

(16)

\[\dot{I} = AI + Bu - G
\]

(12)

The sliding surfaces (S) are equal to the error of state
variables, which can be express as:

\[S = K_{SMP}E_f + K_{SM}\int E_f dt
\]

(13)

Where

\[I = AL + Bu - G
\]
Finally, the control law is given by:

\[
\mathbf{u} = \mathbf{u}_{eq} + \mathbf{u}_{dis} = \begin{bmatrix} u_{eqd} + u_{disd} \\ u_{eqq} + u_{disq} \end{bmatrix} = \begin{bmatrix} u_{eqd} + k_s \text{sign}(S) \\ u_{eqq} + k_s \text{sign}(S) \end{bmatrix}
\]  

(17)

For the sliding mode DC-link voltage controller based on integrator can be determined by substituting the reference line current, is chosen to determine switching surface functions:

\[
S_{dc} = K_{SMPC}(U_c^* - U_c) + K_{SMIC} \int (U_c^* - U_c) dt
\]

And consequently, their temporal derivative is given by:

\[
\dot{S}_{dc} = K_{SMPC}(U_c^* - U_c) + K_{SMIC}(U_c^* - U_c) = 0
\]

Finally, the control law is given by:

\[
i_{eq} = C_i \frac{K_{SMIC}}{K_{SMPC}} (U_c^* - U_c) + U_c^* + K_{SC} \text{sign}(U_c^* - U_c)
\]

(20)

3. Simulation Result

In simulation part, power system is modeled as 3wired 3-phase system by an RL load with uncontrolled diode rectifier. In the circuit, the ac source with frequency of 50Hz. The grid side line voltage is 220V. The line resistor is 0.25Ω. The line inductance of each phase is 1mH. The dc capacitor is 5000μF; the dc voltage is set to be 700V. The switching frequency for three-phase is 15 kHz.

Fig.5. Simulated responses for a step change in the load resistor: a) Load current before filtering Load change at 0.3s. b) Harmonic currents injected by the PWM Rectifier, c) Source voltage, source current.

Fig.6. DC side capacitor voltage and filter current

Fig.7. Current spectrum harmonic: Grid and Load in Phase 1.

The Pv model applied in simulation is as Fig.4. Whose parameters are regulated for normal condition (25°C Temp. and sun radiation G=1kW/m).

**Control of PWM Rectifier with Active Filtering Function**

Fig. 5.A. shows the simulated one phase current load waveform with a step at time 0.3 s.

The current reference of the PWM rectifier and the generated one are superposed in the same Fig. (7).

Fig. 5.C. Fig. 6.Presents the start up the PWM rectifier operation. It is noted the linear currents are sinusoidal and the control technique presents a very good dynamic behavior, Thais thanks to SM regulator behavior used control the DC-link voltage. Under APF operation, the line current becomes almost sinusoidal as well as in phase with line voltage, which gives near-to-unity power factor.

Fig.7. shows the source current spectrum analysis before and after filtering. Before filtering; one can see the current harmonics distortion value was \( \text{THDi} = 27.46\% \) and after filtering it will be \( \text{THDi} = 3.45\% \). Secondly; to show the performance during transient condition the load current is changed at 0.3 s.

**Sliding Mode Control of a Grid Connected Photovoltaic Generation System with Active Filtering Function**

The current reference of the active filter and the generated one are superposed in the same Fig. (8).

The Fig. 9.A. shows the behavior of the current and voltage in Phase 1 of the grid., It is noted the linear currents are sinusoidal and the control technique presents a very good dynamic behavior, almost sinusoidal as well as in phase with line voltage, which gives near-to-unity power factor.

Fig. 9.B. shows simulation results for the DC bus voltage controller. The voltage \( V_{dc} \) on the DC side of the inverter is stable and regulated around its reference.

The THD before filtering for the first line is 27.46 % and becomes 1.79% after filtering.

**4. Experimental Results**

Due to the computational constraints of the TMX320lf2407 fixed-point DSP used in the experimental setup of the PWM rectifier. The sliding-mode-current observers for the grid voltage and the virtual grid flux have been validated experimentally in the linear control systems presented in Fig.10.
5. Conclusion

This paper outlined the modeling and development of the control system for the active filter/PV generation system and PWM rectifier with sliding mode controller based on a Sliding Mode Observer. The results verify the validity of the proposed control scheme. Unity power factor is achieved, active and reactive current are decoupled controlled in the synchronous reference frame and the objective of maintaining balanced voltages in DC-link capacitors is carried out effectively with the proposed SVM, and it offers sinusoidal line currents (low THD) for ideal and distorted line voltage.

The SMO_DPC system constitutes a viable alternative to the conventional control strategies and it has the following features and advantages.

- No line voltage sensors are required;
- It has a lower sampling frequency (than a conventional
  DPC [13]);
- It has good dynamics.
- It offers sinusoidal line currents (low THD), for ideal and distorted line voltage.
- No current control internal loops
- Decoupled active and reactive power control
- Robustness to grid voltage distortions.
